

Test-1

- Create one page (not in the app component)
 - in that page take one number input field and submit button
 - implement proper validation (text box should accept only numbers)
 - on click of submit button redirects to another page with an entered number in the text box in the URL(using query parameter)
 - in that take 8 controls
 - all the fields are required
 - this form should be a template-driven form
 - 1) three textboxes with first name middle name and last name
 - 2) one textarea which is disabled but the value is a combination of first name last name middle name
 - 3) number input for age
 - 4) radio button for gender
 - 5) the checkbox for hobbies with 5 value
 - 6) dropdown for company list with minimum 8 values
 - 7) all the control should be properly designed with the use of bootstrap
 - 8) three buttons one is back one is clear one is submit
 - on back redirect to the main screen
 - on clear click clear all the filled data
 - on submission store the data in local storage and redirect to another page with the same id
 -
 - in that, we have another form with the same control as the above form but that is in reactive form
 -
 - we have one more button to get data and on click of that we will get data and bind it to the form
 -
 - we can change form values and submit it, so it will update the local storage json
 -
 - and on submit again we will redirect to the main page
 -
 - On the main page if I will enter the already added id we will get the next screen with stored data
